

Utilizing Containers to Simplify your Oracle DevOps

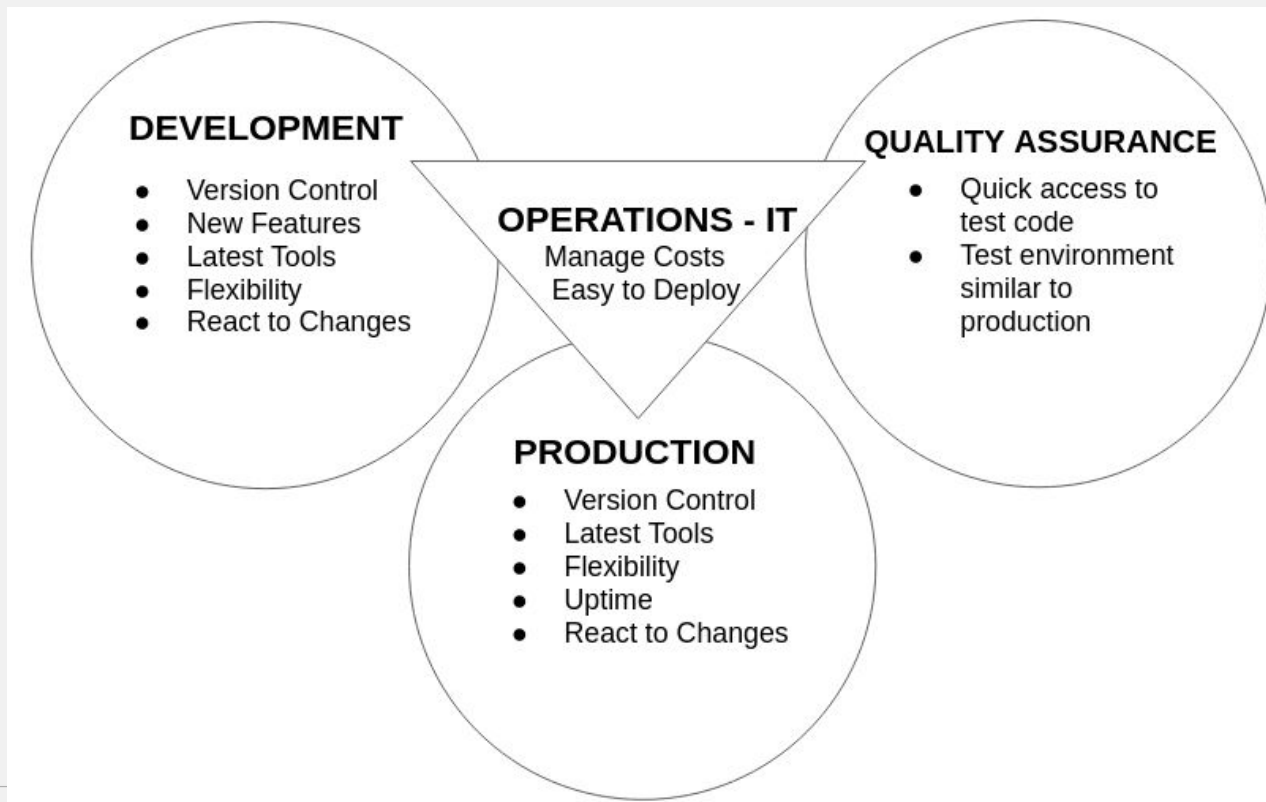

Roger Lopez
Sanjay Rao
Oct 1st, 2017

Agenda

- Underlying Problem
- Understanding DevOps
- Containers
- Using containers to simplify DevOps

The Underlying Problem

Typical Ecosystem

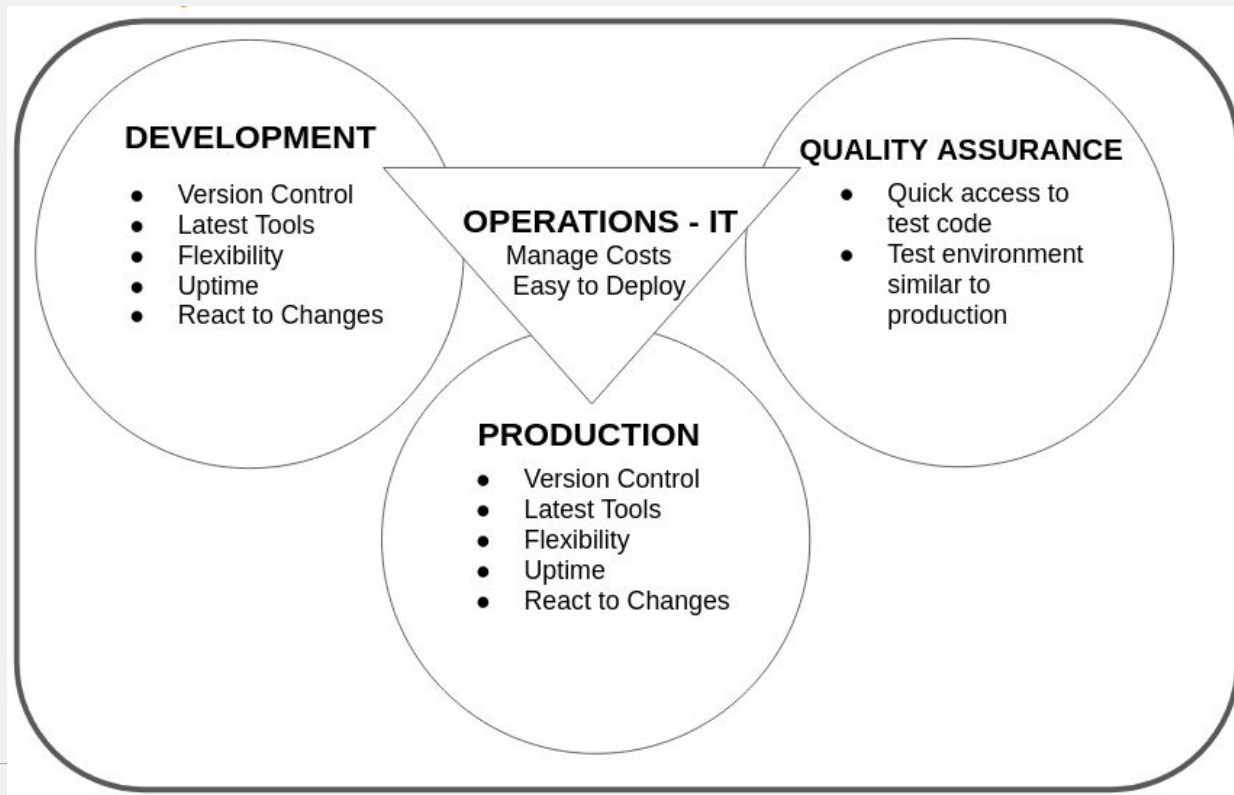

Understanding DevOps

DevOps

- It is a concept, practice
- DevOps Movement - CAMS
- Better collaboration between Developers and Operations (IT) to facilitate
- Software version management
- Easy transition between the various stage of Software Lifecycle
- Software delivery and Infrastructure changes
- Delegate control down to each Business Unit

DevOps Environment

Containers

Linux Containers

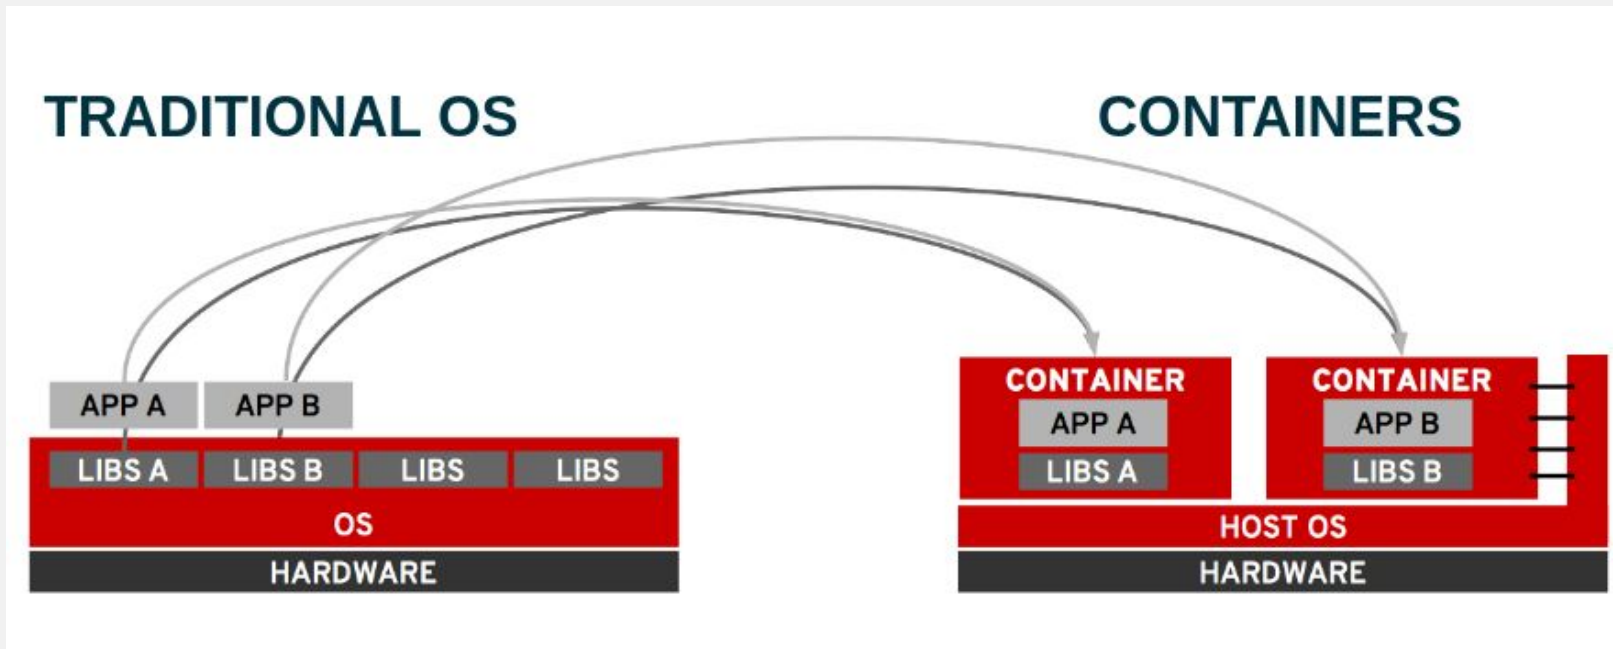

- What are Linux Containers (LXC)?
 - An OS level virtualization method that allows running multiple isolated environments for applications (containers) on the same host.
- How is this accomplished?
 - By using the Linux kernel's Cgroups and isolated namespaces

Linux Containers

Benefits:

- Complete isolation from other processes, applications and containers running on the same host
- Resource friendly
- Platform independence
- Portability
- Resource control

Containers are an OS Technology

Containers vs Virtual Machines

- User space libraries
- More Density
- Performance on par with platform
- No live Migration
- Entire OS
- Some performance loss due to abstraction of certain functions
- Live Migration

Considerations when moving Legacy Applications to Containers

- Look for ways to split up your legacy application
- Understand the different application configurations
- Logging

Moving Legacy Applications to Containers

- Provide all the commands required to setup and install all the application dependencies within a Dockerfile
- Build an image based upon that Dockerfile, i.e. “gold image”
- Start your container
- Run your application as you would on bare metal environment

Building a Container Image

Building a Container Image

- Ensure that the image is validated or comes from a trusted source
- Get the required OS runtime image for the application
- Install all the runtime libraries and software that is required to be part of the container image

Trusted Registries

```
srao@localhost:~  
File Edit View Search Terminal Help  
-bash-4.2# docker info  
.  
.  
.  
Storage Driver: devicemapper  
Pool Name: docker_vg-docker--pool  
Pool Blocksize: 524.3 kB  
Base Device Size: 21.47 GB  
Backing Filesystem: xfs  
Data file:  
Metadata file:  
Data Space Used: 13.5 GB  
Data Space Total: 61.78 GB  
Data Space Available: 48.29 GB  
Metadata Space Used: 1.085 MB  
Metadata Space Total: 109.1 MB  
Metadata Space Available: 108 MB  
.  
.  
.  
Registries: registry.access.redhat.com (secure), docker.io (secure)  
~  
~  
~  
~  
~  
~
```

Build the Container Image - Dockerfile

- The Dockerfile is a text document that contains all the commands a user would run to build their application.
- An example Dockerfile to build an Apache server can be found here: <http://bit.ly/2naWwez>
- Let's take a closer look!

Build the Container Image - Dockerfile

- An example of a more complex Dockerfile to build a Container can be found here: <http://bit.ly/2nWxe3C>
- Let's take a closer look!

Build the Container Image

- Once the Dockerfile is ready, within an empty directory that only contains the Dockerfile, build an image from a Dockerfile
- Syntax:
`docker build -t <name>:<tag> .`
- Example:
`docker build -t oast:12c .`
- Confirm the image is ready using
`docker images`

Building and Running a Container Image

- Output of docker images

```
-bash-4.2# docker images
REPOSITORY          TAG          IMAGE ID          CREATED           SIZE
oast                 12c         d5efd9cale74     About a minute ago 5.929 GB
oracle/database     11.2.0.2-xe 8c6da4b7d1bd     23 hours ago     1.122 GB
registry.access.redhat.com/rhel7/rhel-tools  latest      264d7d025911     8 days ago       1.488 GB
registry.access.redhat.com/rhel7            latest      41a4953dbf95     13 days ago      192.5 MB
docker.io/oraclelinux 7-slim      f005b5220b05     2 weeks ago      114.3 MB
```

- Use the docker run command to a container:

Example:

```
docker run -it --name oast -d -v /var/oast:/perf1 oast:12c
```

- Set SELinux context for external volume:

```
chcon -Rt svirt_sandbox_file_t /var/oast
```

Building and Running a Container Image

- Check that the container is running using:
`docker ps`
- Attach to the docker container via:
`docker attach oast`

PRO Tip: Detach from a running container using CTRL+P,CTRL+Q

Modernizing Traditional Applications

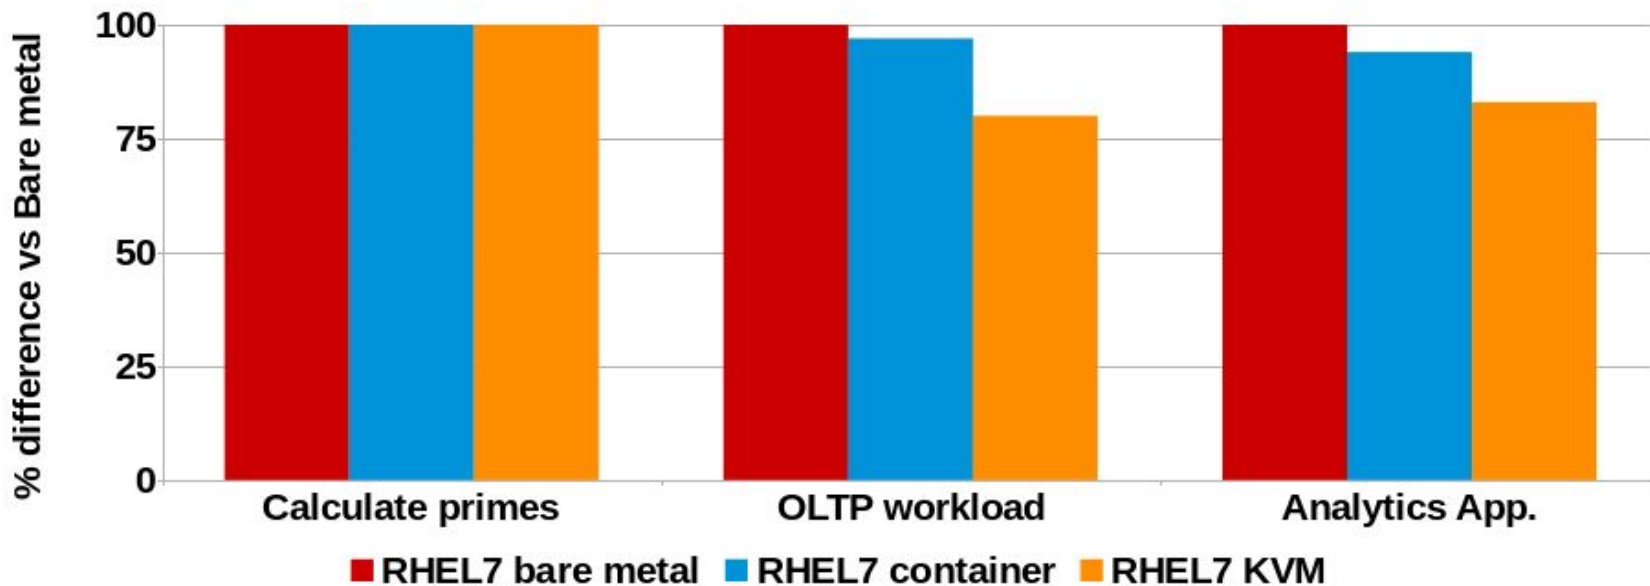

Modernizing traditional applications

- Break down monolithic legacy applications into components
- Smaller footprint
- Better resource control
- Reduced downtime
- Scalable
- Faster Development / Testing / Deployment
- Performance

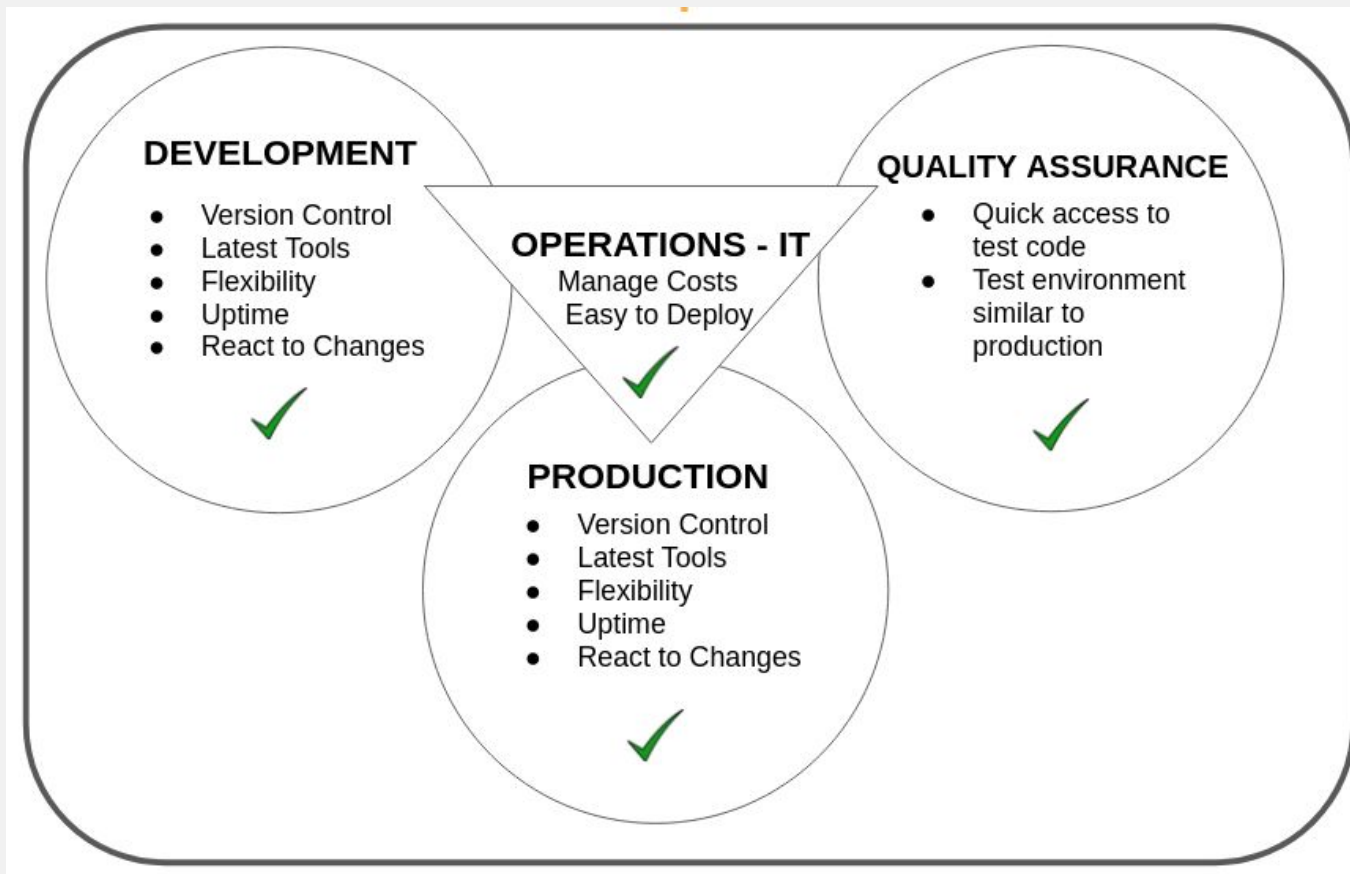

Performance of Large “Expensive” Apps

Container performance across multiple workloads

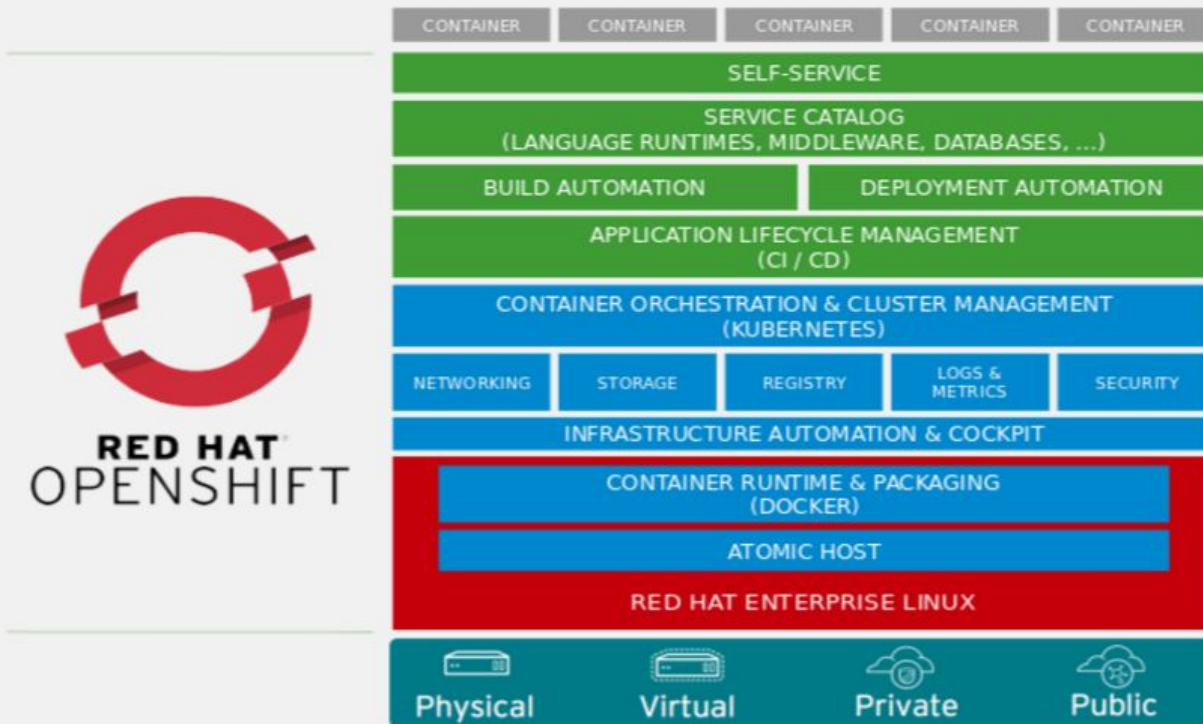

Time to Complete Test Workload
Higher is Better

Containers for DevOps

Build, Deploy, and Manage Containerized Apps
